NOVA CRYPTO

Crypto, without the confusion.

Website Master Prompt & Product Blueprint

A professional, original crypto market-data, education, portfolio and paper-trading platform concept.

Default audience: beginners and everyday users, with India/INR as the default experience.

1. PRODUCT VISION

Build an original cryptocurrency information and learning platform called **NOVA Crypto**, with the tagline **“Crypto, without the confusion.”** The product should feel trustworthy, modern, simple and data-driven. It may take broad inspiration from the usefulness of major crypto-market websites, but it must not copy their branding, layouts, text, icons, code, proprietary assets or visual identity.

2. CORE GOALS

Create a platform that helps users understand crypto markets rather than simply displaying prices. Prioritize clarity, transparent data, beginner education, risk awareness, portfolio tracking and safe simulated practice. The first release should be informational and simulated only: no real-money deposits, withdrawals, custody or exchange execution.

3. DESIGN SYSTEM

Use a premium fintech/crypto aesthetic: clean cards, strong typography, generous spacing, subtle gradients, restrained motion and excellent mobile responsiveness. Support dark and light themes. Use an original NOVA visual identity with a simple geometric logo and consistent iconography. Avoid visually cloning Binance, CoinMarketCap or any other competitor.

4. MAIN NAVIGATION

Navigation should include: Home, Markets, Compare, Paper Trade, Portfolio, Learn, News/Events, and Ask NOVA. Add Sign In/Register and a profile/security area. On mobile, use a compact bottom or collapsible navigation pattern with the most important actions easily reachable.

5. HOMEPAGE

Show a market snapshot with total market capitalization, 24-hour volume, BTC dominance, ETH dominance, trending assets, top gainers and top losers. Add a daily market briefing written in simple language, a market sentiment/risk section, featured educational content and clear calls to explore markets or start a paper portfolio.

6. MARKETS

Create a searchable, sortable and filterable market table. Initial examples can include BTC, ETH, SOL, XRP and USDT, with architecture designed to support many assets later. Display symbol, name, price, 24h change, market cap, volume, circulating supply and an appropriate risk/volatility indicator. Default currency should be INR, with optional currency switching.

7. COIN DETAIL PAGE

Each asset page should provide price and historical charts, market statistics, supply information, description, use case, ecosystem/technology overview, historical performance, volatility, major risks, relevant events and beginner-friendly explanations. Separate facts from interpretation and show data timestamps/source labels where possible.

8. COMPARE

Allow users to compare 2–5 crypto assets side-by-side. Include price, market cap, volume, supply, historical returns, volatility, drawdown and other relevant metrics. Use clear charts and plain-language interpretation. Never

imply that historical performance guarantees future returns.

9. PAPER TRADING

Create a simulation using virtual funds only. Users can select an asset, choose buy/sell quantity, review an order preview and execute simulated trades. Track virtual cash, holdings, average entry, unrealized/realized P&L; and transaction history. Clearly label the feature as simulated and prevent accidental presentation as real trading.

10. PORTFOLIO

Provide a portfolio dashboard showing total simulated value, allocation, P&L;, performance over time and asset concentration. Include educational risk prompts such as diversification, volatility and drawdown awareness. Keep all calculations auditable and explain how values are calculated.

11. ASK NOVA

Add a beginner-friendly AI explainer experience called “Ask NOVA.” It should explain crypto concepts, market metrics and chart terminology in plain language. It should distinguish education from personalized financial advice, disclose uncertainty, avoid guaranteed-return claims and encourage users to verify important information.

12. LEARN CENTER

Build a structured learning hub from beginner to advanced levels. Topics should include blockchain basics, wallets, exchanges, market cap, liquidity, stablecoins, volatility, risk management, scams, security, portfolio concepts and responsible investing. Use short lessons, examples, glossaries, quizzes and visual explanations.

13. NEWS & EVENTS

Provide a news/events area with dated articles, market-moving events, token/ecosystem updates and educational context. Every external data source should be attributable. Avoid sensational headlines. Add filters by asset and topic and clearly distinguish news reporting from NOVA analysis.

14. USER ACCOUNTS & SECURITY

Support secure registration/login, session management, password reset, optional MFA, account settings and device/session management. Never expose API keys or secrets in frontend code. Protect personal data, use secure server-side authentication and apply rate limiting, validation and logging.

15. INDIA / INR EXPERIENCE

Make INR the default display currency for the India-focused experience. Format Indian numbers naturally and provide clear explanations of fees, taxes, risks and regulatory considerations without presenting legal or tax information as professional advice. The product should remain useful internationally through configurable currencies and locales.

16. TECHNOLOGY STACK

Recommended architecture: Next.js + React + TypeScript for the web application; Tailwind CSS for styling; a PostgreSQL database; server-side API routes/services; a reputable market-data provider; secure authentication; caching and background jobs for market-data refreshes. Keep provider keys and secrets server-side. Design the data layer so providers can be changed without rewriting the UI.

17. DATA & DATABASE ARCHITECTURE

Suggested entities include users, sessions, assets, asset_metrics, historical_prices, market_snapshots, watchlists, portfolios, portfolio_positions, simulated_orders, transactions, educational_articles, news_items, events, alerts and audit/security records. Store timestamps, source/provider metadata and enough information to reproduce portfolio calculations.

18. ACCESSIBILITY & PERFORMANCE

Target WCAG-conscious accessibility: keyboard navigation, semantic HTML, visible focus states, readable contrast, meaningful labels and screen-reader-friendly charts/tables. Optimize for mobile networks, lazy-load heavy components, cache market data appropriately and provide graceful loading/error/empty states.

19. SAFETY & PRODUCT BOUNDARIES

The initial product must not process real-money transactions. Do not imply that NOVA is an exchange, custodian, broker or licensed financial adviser. Add prominent risk disclosures where appropriate. For any future real-money functionality, conduct jurisdiction-specific legal/compliance review, security audits, custody planning, operational controls and licensing analysis before launch.

20. DEVELOPMENT PHASES

Phase 1: brand, responsive shell, homepage and markets.
Phase 2: coin pages, historical charts, compare and search.
Phase 3: accounts, watchlists, portfolio and paper trading.
Phase 4: Learn, News/Events and Ask NOVA.
Phase 5: performance, accessibility, security hardening, analytics, testing and deployment.

21. BUILDER INSTRUCTION

When using an AI coding/building tool, paste this document as the master product brief. Instruct the builder to produce a working, original application rather than a static mockup. Build reusable components, realistic loading/error states, responsive layouts and clean API boundaries. If a data provider is not configured, use clearly labeled mock/demo data rather than inventing live prices.

22. FINAL ACCEPTANCE CHECKLIST

Before launch, verify: responsive mobile/desktop layouts; original branding; working search/filter/sort; accurate calculations; clear data timestamps; secure authentication; no client-side secrets; paper trading isolated from real funds; accessible forms and charts; graceful API failure; clear risk disclosures; source attribution; unit/integration tests for portfolio math; and a production-ready deployment configuration.

COPY-PASTE MASTER BUILD PROMPT

Act as a senior product designer, full-stack engineer and fintech UX architect. Build NOVA Crypto, an original crypto market-data, education, portfolio and paper-trading web application. The tagline is “Crypto, without the confusion.”

Priorities:
1. Make crypto understandable for beginners.
2. Use an original premium fintech visual identity; do not copy competitor branding, layout, code or proprietary assets.
3. Default to INR and provide an India-friendly experience.
4. Show transparent market data with timestamps and source/provider labels.
5. Include Home, Markets, Coin Details, Compare, Paper Trade, Portfolio, Learn, News/Events and Ask NOVA.
6. Paper trading must use virtual funds only.
7. Use secure authentication and never expose secrets in client-side code.
8. Build responsive, accessible, fast interfaces with excellent empty/loading/error states.
9. Separate factual data, educational explanations and analysis.
10. Do not present historical performance as a guarantee or personalized financial advice.

Recommended stack: Next.js, React, TypeScript, Tailwind CSS, PostgreSQL, server-side APIs and a reputable market-data provider. Design the backend so the data provider can be replaced later.

Deliver a production-quality foundation with reusable components, clean database models, API boundaries, validation, testing strategy and deployment guidance. If live data credentials are unavailable, use clearly labeled demo data. Do not invent live prices or claim simulated trading is real trading.

The final product should feel trustworthy, modern, educational and simple enough for a first-time crypto user while still giving advanced users useful market and portfolio tools.
